1. OBJECTIVES

- Implementing of a network with traffic shaping and polishing by using OMNnet++ Simulator with INET Framework.
- Designing the network using 15 routers, a source host and destination host.
- Creating multiple paths between source and destination in a network topology.
- Configuring OSPF routing protocol on all the routers.
- Generating three different application such as audio, voice and video.
- Simulating to calculate end-to-end delay, queuing delay, packets dropped, and packet sent and received.

2. INTRODUCTION

The main aim of this project is to test how the traffic shaping and policing works to enhance the network resource efficiency and provide better services. It also helps us to understand the Quality of Service of the network. In this project, OMNnet++ simulator is used for the implementation for different types of network applications such as audio, voice and video.

3. BACKGROUND

Traffic shaping and policing are separate traffic conditioning systems. Both methods compare the levels of various traffic groups to a regulation or service level agreement (SLA). In terms of bandwidth, traffic rates, reliability, availability, QoS, and billing, it is typically set up between a company and a service provider.

Traffic shaping is also called as packet shaping. A congestion method and bandwidth management used in computer networks regulates data by delaying the flow as desired. Traffic shaping is the process to alter the flow of packets which ensures that a packet conforms specific specification. It police the incoming packets which can shape their traffic prior to passing it to the other network. It uses data classification, quality of system, policy rules, and queuing techniques to ensure proper bandwidth for audio, voice and video. Leaky bucket traffic shaper is used for shaping the packets in which it consist of buffering the incoming packets. There is possibility of packet loss due to buffer overflow. The incoming packets are buffered and smoothed out.

Traffic policing also known as rate limiting which monitors the flow of traffic continuously to ensure they meet the criteria of the traffic contract. The network can discard or tag the packet by giving it to low priority when the traffic contract is violated. The packets are dropped when there is a congestion. Leaky bucket algorithm is most used mechanism for policing where it can be used to police the arrival rate of packet stream. The bucket has a specific rate and specified depth for incoming packets. This is applied on the ingress bound traffic of ISP.

Traffic shaping buffers traffic that reaches the policy/agreement. Excess traffic is either reduced or marked at a lower level by policing (re-marking). These traffic conditions are deployed at the network edge. The main purpose of the traffic policing to limit the rate that is being sent in the network, send different traffic classes at different rates.

Drop tail queuing is used which is a passive queue management type where it stores the packets until the buffer gets full. When the buffer is full, the packets are dropped. This is based on FIFO mechanism to schedule the packets.

Round robin is utilized when network shares a minimum bandwidth or latency requirements, the bandwidth is guaranteed to congestion point. Queue serviced in round robin are assigned for each queue. This is done for the purpose of admission control whether to provide the flow to accepted or rejected. The flow negotiates into the network by making a contract. Through this admission control checks if sufficient resources are available for the data flow.

In this project, we have implemented these mechanisms using OMNnet++ simulator. There are 15 routers along with one source and one destination. There multiple paths connecting between host source and destination host. As Shown in figure below.

Figure 1: The design of the network topology

The policing is done Router 1 and shaping is done on Router 3. The filters.xml file and OSPFConfig.xml are used. The results are obtained in three different drop tail without shaping and policing, drop tail with shaping and policing and round robin with shaping and policing.

4. RESULTS

After simulation, new files will be created under the src file name vec and sca. Double clicking on that file we can get .anf file where we can view our results.

A. END TO END DELAY ,PACKET SENT AND RECEIVED FOR WITHOUT POLICING AND SHAPING

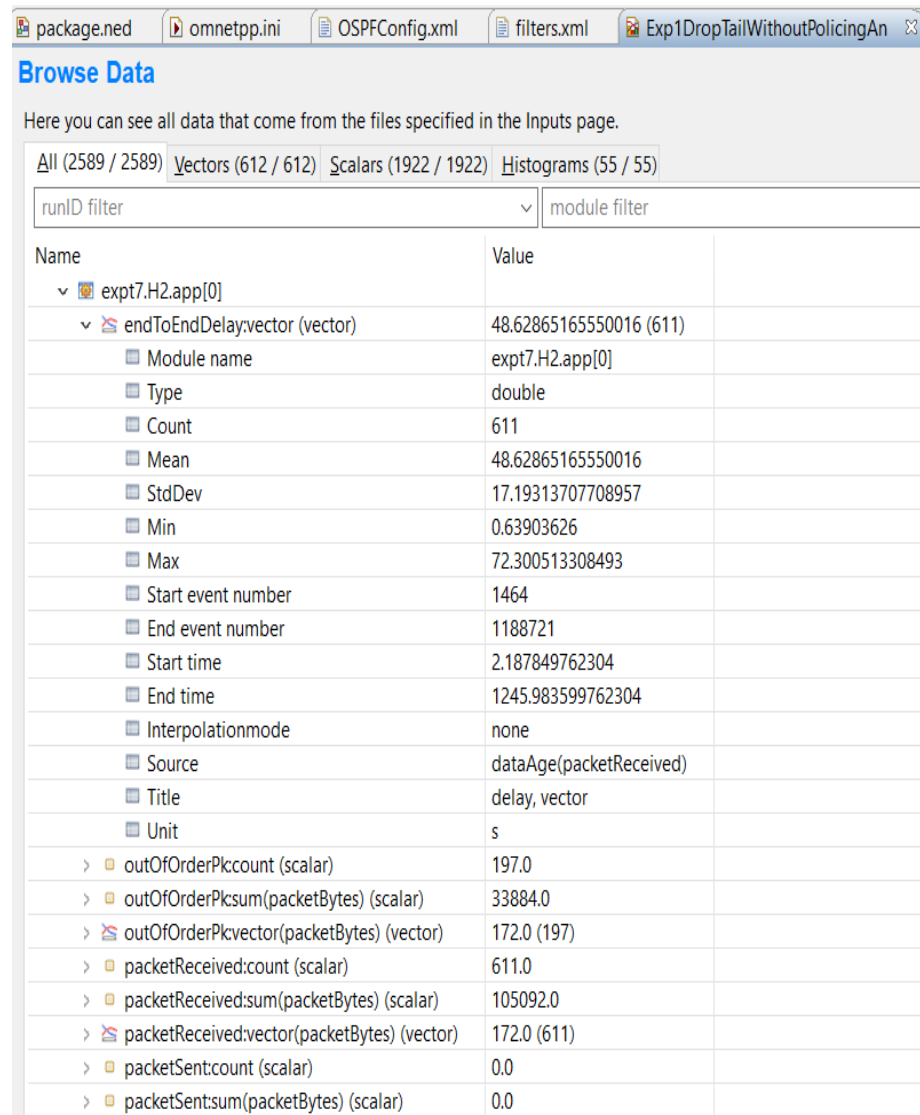

Figure 2. End- to end delay for Drop tail without policing and shaping for application 0.

The end-to-end delay vector data is 48.62 for the application 0 that is voice streaming. The count is 611. The packets received is 611 in scalar and 172 in vector. Out of order is 197 in scalar.

Graph 1 . End- to end delay for Drop tail without policing and shaping for application 0.

Figure 18. The queuing time for application 1 at Router 3 is 0.01.

5. DISCUSSION

Policing is done on Router 3 and shaping is done Router 0. From the above results, end-to-end delay is more for application 1 i.e for voice application when compared to video, TCP traffic. The queuing delay is more in application 0 at router 3 for all the three configurations. The count is least in TCP traffic for all the applications in all three configurations. The OSPF is configured for all the routers.

6. CONCLUSION

This project allowed to learn how the policing and shaping works in a network. The use of OMNnet++ simulator helped to understand the real- time working of the network topology. It helped to understand the use of OSPF Configuration on routers. It also helped us to understand the round robin mechanism used in the network.

7. Difficulties Faced in implementing RSVP

- Not able to configure rsvp on all the routers.
- Not able to implement fec file properly.
- Not sure, how to implement with multiple sources and destination hosts.
- Faced some errors while building the project and got implicit serialization.
